**ABSTRACT**

The neurocurative potentials of *Ficus asperifolia* leaf extract against carbon tetrachloride-induced toxicity in rats was investigated. Thirty rats were grouped into five. In each treatment groups, was *F. asperifolia* extract of 100, 200 and 400 mg/kg body weight was administered by oral gavage for three weeks before exposure to neurotoxin-carbon tetrachloride (CCl₄) 3 mL kg⁻¹ i.p. were used to test neurocurative potentials of the extract. Antioxidant enzymes namely reduced glutathione (GSH) levels, catalase (CAT), glutathione peroxidase (GPx), superoxide dismutase (SOD), and malondialdehyde (MDA) were assessed and histological examinations of the tissues were monitored. Results showed significant decrease in the antioxidant enzymes and an elevation in MDA. *F. asperifolia* showed a significant brain protective influence by the lowering lipid peroxidation and increasing antioxidant enzymes and glutathione. Furthermore, histological alterations were ameliorated in CCl₄-induced treated rats with *F. asperifolia*. These indicates that *F. asperifolia* possesses neurocurative potentials and can efficiently inhibit CCl₄-induced oxidative damage.

**KEY WORDS:** *Ficus asperifolia* Miq leaves, carbon tetrachloride, aqueous extract, neurocurative, enzymes.

1. INTRODUCTION

Carbon tetrachloride (CCl₄), a clear, colourless, volatile, heavy and non-flammable industrial liquid, reportedly used to induce free radical toxicity in different tissues of experimental animals (Khan, 2010). CCl₄ is biotransformed to tri-chloromethyl-free radical (CCl₃ or CCl₂OO) (Preethi, 2009) thus initiating the chain reaction process (Adewole, 2007; Adewole, 2012). The most prominent mechanism of CCl₄ is in the generation of radicals in tissue damage (Sahreen, 2011; Khan, 2011). This free radical and related reactive species leads to oxidative stress, which produces major interconnected changes of cellular metabolism, increases the serum marker enzymes, and lipid peroxidation (Bhadouria, 2008). In other to maneuver itself from the effects of free radicals, endogenous enzymatic and non-enzymatic systems were employed, but when the generation of free radicals is excessive, mechanisms that are more protective may be of a great importance (Tirkey, 2005). Antioxidant systems that protect the body include the antioxidant nutrients and enzymes (Sreelatha, 2009). Antioxidant have been used to study CCl₄ toxicity in other to protect tissue-induced damage by breaking the process of lipid peroxidation. Numerous crops and fruits are good sources of antioxidant, which protect body against tissue induced oxidative stress (Ogeturk, 2005). In Africa, *Ficus asperifolia* have been used as an anthelmintic and laxatives (Soforowa, 1996). *Ficus asperifolia* has been shown to possess many pharmacological and physiological activities such as antioxidants (Ojo and Akintayo, 2014). Hence, the need to evaluate the neurocurative potential of *Ficus asperifolia* (Miq) against carbon tetrachloride induced toxicity.

2. MATERIALS AND METHODS

**Plant material:** Fresh sample leaves were procured from local suppliers in Ado-Ekiti (Ekiti State) and authenticated at the Department of Plant Sciences, Federal University of Agriculture, Abeokuta, Nigeria and voucher specimen has been deposited. The leaves were dried and powdered with an electric grinder.

**Extraction:** 50 g of the powdered sample was extracted with distilled water of 500 ml for 48 hours. The filtrate was measured and evaporated to dryness using a freeze dryer to obtain 12 % yield.

**Experimental animals:** Thirty male rats (140 – 180 g) were maintained in the Laboratory Animal Unit of the College of Sciences, Afe Babalola University. They were fed with standard diet and water *ad libitum*. However, male rats were used for this experiment because of their constant metabolism to the female rat’s physiology. Animals were acclimatize for a week. The care and handling of the rats are used follows the internationally accepted standard guidelines and were approved by Afe Babalola institutional review board.

**Doses:** The dose selection for extract of *F. asperifolia* was as a result of the acute toxicity study. According to the method of Ojo (2014) with a slight modification, experimental dose of 100, 200 and 400 mg/kg that equal to 1/40, 1/20 and 1/10 of the maximum possible dose of the extract in rats that were selected.

**Experimental induction of brain damage:** CCl₄ was dissolved in groundnut oil in the ratio 1:1 v/v. Brain oxidative damage was induced in rats at a dose of 3 mL/kg CCl₄ (Theophile, 2006).
Neurocurative activity: Thirty male rats were randomly grouped into five of six animals, each. Rats of the 1st (normal control) group and 2nd (CCl₄-intoxicated) groups received a dose of 3 mL/kg. The 3rd, 4th and 5th groups were administered with the *Ficus asperifolia* extract. All medications were administered orally by oral gavage for three weeks. Two hours after the last dose of extract, normal control rats were given groundnut oil (3 mL/kg, SC), while rats in the 2nd to 5th groups received CCl₄ (3 mL/kg, SC). After 24 h of CCl₄ injections, blood sample (2 mL) was collected in previously 1335 abled samples tubes and allowed to clot for 30 min at room temperature. Serum was separated by centrifuging at 10,000 rpm for 5 min. Brain tissues were dissected out into two parts for determination of antioxidant status and for histopathological examination.

Assessment of CCl₄ mediated oxidative stress: Lowry (1951), alanine and aspartate aminotransferases (ALT and AST) activities were determined by Mohun and Cook (1957), Reitman, and Frankel (1957) determined Protein contents of the samples. Buege and Aust (1978) determined the lipid peroxidation level. McCord and Fridovich (1969) measured superoxide dismutase activity. Catalase was determine spectrophotometrically by Aebi (1974). Reduced glutathione level by Beutler (1963). This method is on developing a stable (yellow) color when 5',5'-dithiobis-(2-nitrobenzoic acid) (Ellman’s reagent) mix to sulfhydryl compounds. Glutathione peroxidase by Rotruck (1973).

Histopathology of tissues: The brains tissues from the rats were fixed with 10% formalin. The sections of the tissues were stained with hemotoxylin dye for histopathological observation.

Statistical analysis: Statistical analysis was performed using GraphPad Prism 5 statistical package (Graph Pad Software, USA). Data were analyzed using a statistical software package (SPSS for Windows, version 20, IBM Corporation, USA) using Duncan multiple range post-hoc test. Values of mean ± standard deviations in triplicates were considered significantly different at p < 0.05.

3. RESULTS

While animals that received very high dosage did not die, other signs of toxicity were noticed 2 - 4 hours after extract administration. There were decrease locomotion, writhing, constipation and decreased in sensitivity to touch. In addition, there was decreased feed intake and prostration 15 hours after extract administration.

Administration of CCl₄ to rats showed significant elevation of brain marker enzymes (ALT, AST and ALP) in their serum after 24 hours of intoxication. Administration of the *F. asperifolia* aqueous extract at the dose used for three weeks prior to CCl₄, exhibited a significant neuroprotective activity, resulting in decreased elevated serum activities of brain marker enzymes as shown in Table 1 when compared to CCl₄ untreated rats. The toxicity induced by CCl₄ in the brain tissues was assessed by measuring the antioxidant defense enzymes like SOD, GPx and CAT, GSH (Table 2) and MDA levels (Table 3). Table 3 showed that administration of CCl₄ induced reduction in the activities of SOD, GSH, GPx and CAT enzymes when compared to the control group. Although, it increased the MDA level in brain tissues Table 4. Pre-administration with *F. asperifolia* extract to group three, group four and group five reduced the toxicity of CCl₄, evident from the observed differences shown in these groups.

Histopathological Studies: The histology of brain tissues slide of CCl4-untreated rats showed severe spongiosis, mild congestion, severe necrosis and hemorrhage at the meninges (Figure 1). Administration of F. asperifolia extract to group three, group four and group five might have confirmed the neuroprotective activity as a significant recovery of neuronal damage, and decreased necrosis was persistent against CCl4-induced toxicity in rats, which is similar to their control. The histological results further corroborated the biochemical findings, suggesting the useful effects of Ficus asperifolia in CCl4-induced toxicity in rats.

DISCUSSION

Oxidative stress is involved in many neurological diseases. Gupta, (2003) reported that free radical increases during seizures (Gupta, 2003), suggesting their importance in the pathogenesis of epileptic seizures (Patel, 2004). Similarly, increase in MDA levels and a reduction in thiol groups of animals that had CCl4-induced damage was observed. It was well demonstrated that production of ROS, including superoxide anions and hydrogenperoxide,
in the brains of animals subjected to seizures (Suha, 2001; Rodrigues, 2012). Hence, we investigate the protective influence of the Ficus asperifolia against CCl₄-induced toxicity in rats. However, results show that extract possesses protective action against oxidative induced damage by the potent toxin CCl₄.

However, administration of the extract up to 4000 mg/kg did produce other signs of toxicity, which includes decrease locomotion, writhing, constipation and decreased in sensitivity to touch. Therefore, F. asperifolia leaf extract can be considered as highly safe (Ojo et al., 2013).

Furthermore, enzymes (ALT and AST) and the histological changes were used to evaluate the F. asperifolia neurocurative potentials. Consistent with reported studies, results confirmed that CCl₄ exposure damaged the brain, as seen by the elevation in the serum aminotransferase activities and morphological changes seen in the brain sections (Renguadevi and Prabu, 2010). Reduction of these enzymes with F. asperifolia could be due to the stabilization of plasma membrane and repair of brain damage caused by CCl₄ similar to that reported by (Ojo et al., 2014a).

The effect of F. asperifolia on the brain toxicity by CCl₄ as determined by the antioxidant defense enzymes like catalase (CAT), superoxide dismutase (SOD), glutathione reduced and peroxidase (GSH and GPx). Pretreatment with F. asperifolia extracts significantly (p<0.05) increase tissue parameters with significant (p<0.05) increase to CCl₄untreated group (Table 2). Furthermore, it can be confirmed by measuring malonaldehyde levels. The MDA levels were significantly (p<0.05) elevated in CCl₄ group than with normal group (Table 3). Administration with F. asperifolia significantly (p<0.05) decreased the levels to CCl₄ untreated group suggesting that F. asperifolia has antioxidant activity as reported by (Ojo and Akintayo, 2014).

Histological changes reveal that CCl₄ caused abnormal ultrastructural in the brain tissue, including spongiform necrosis, nuclear vacuilation pycnosis and lymphocytic inflammatory changes. Sequel to histopathological observation in F. asperifolia treated CCl₄ intoxicated rats; CCl₄ has recovered the observed pathological impairments by CCl₄ to be significant, which indicates that F. asperifolia is capable of preventing the neuronal toxicity.

The findings elucidate the neurocurative potentials of Ficus asperifolia (Miq) leaf extract on the brain. The possible mechanism of neuro-protection may be attributed to presence of phyto-constituents in the leaves of this plant (Ojo, 2014b).

4. CONCLUSION

In conclusion, F. asperifolia exhibited a significant curative action against CCl₄-induced neurotoxicity in rats. The leaf extract also shows neurocurative potential; it protected the rat brain against CCl₄-induced neurotoxicity and enhanced the antioxidant status of the brain.
